} [  Open ]
```

2.2 Track Topology

SPT2TS-122297 - The railway system's determining feature is the network of connected tracks. The railway network topology is defined by the tracks and the connections that allow trains to travel from one track to the next.  Content to be approved]

2.2.1 Design decisions

SPT2TS-49043 - The topology shall be clustered into so-called 'TopoArea(s)' where in subsets of track topologies are defined. This clustering allows high flexibility while handling infrastructure data for the consuming systems. For instance, a Traffic Management System responsible for three different interlockings can require several topo areas to handle operations in comparison to the topo area requirement for the interlockings. Hence, it also offers a great deal of data separation in terms of identifying relevant areas for consuming systems. [🔗 Content to be approved]

SPT2TS-49041 - The track edges shall be defined with implicit orientation direction from start to end based on their length. This implicit definition improves the understanding of track edge definition in the model and paves as a smoother way for the specification of track edge links. [🔗 Content to be approved]

SPT2TS-49040 - The track nodes are omitted from the SD1 data model since the information provided by this model element (e.g., start and end of track edge, track navigability) can be sufficiently covered by other existing model elements (e.g., Track Edge and Track Edge Links) in the SD1 Model. Hence, it was ruled out on the grounds of redundancy and optimisation of the data volume of the model. For more information in Track Nodes, see 📄 SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69] [🔗 Content to be approved]

2.2.2 Topology

SPT2TS-49039 - Topo Area: A topo area is a container for rail network topology to manage (e.g. publish) parts of the infrastructure. This lets user agree on subsets of topology that is of concern to their particular use case. Its purpose is to contain subset(s) of the network topology. Topo areas consist of a list of track edges along with track edge links. [🔗 Content to be approved]

SPT2TS-49010 - LinearElement: Linear element is a linear object that defines an uninterrupted stretch of a railway track without divergence or convergence. A linear element is defined along the centre line of the 2D or 3D track alignment and has a finite length. A LinearElement is associated with NetRelation to determine navigabilities between linear elements.

The linear elements have an implicit direction. This direction is defined with respect to their start and end locations. The default orientation direction is start to end. The start of track edge is identified as the point where length is 0 and the end of track edge is identified as the point where length is maximum. The maximum length is given by the parameter 'length' in LinearElement class. The start/end of linear element shall correspond to the location of a simple point (switch), or any form of end of track. The start/end of linear element corresponds to the tangent/secant point or the geometric start location of a simple point.

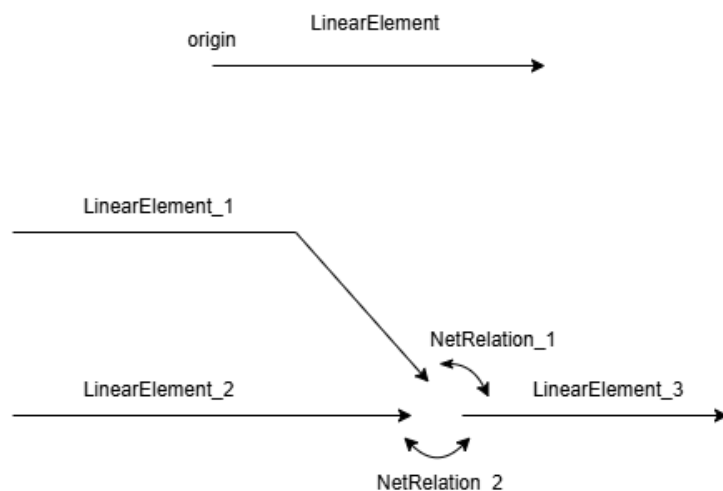

Figure 1 Topological representation of Track Edge

The following equivalent classes from other models can be referred to:

- LinearNetElement, or LinearElementWithLength at MICRO Level (the term "NetElement" is avoided to support comprehensibility and to meet [SPT2TS-154](#)) in [SPT2TS-10 - RSM - RailSystemModel](#)
- [SPT2TS-9 - LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)
- LinearNetElement in [SPT2TS-8 - EULYNX Data Model \(dataprep.eulynx.eu\)](#)
- Track Edge in [SPT2TS-7 - RCA Digital Map – MAP Object Catalogue \[RCA.Doc.69\]](#)
- LinearElement in ERA vocabulary

[ Open]

SPT2TS-49008 - NetRelation: NetRelation defines a relation between two linear elements along which a train can run. NetRelations determine which travel options are permitted at points and which are excluded. They are necessary to eliminate the physically impossible train movements (e.g. a movement from the left to the right branch of a point). A turn table can be modelled as well and would be added to the model as a functional element as soon as requirements for it are provided.

The following equivalent classes from other models can be referred to:

      ]
    }
  ]
}
```

2.2.2.1 Linking Areas

SPT2TS-123555 - From the model point of view the linking of two areas happens by using TrackEdgeLinks referencing TrackEdge of the neighbour Area.

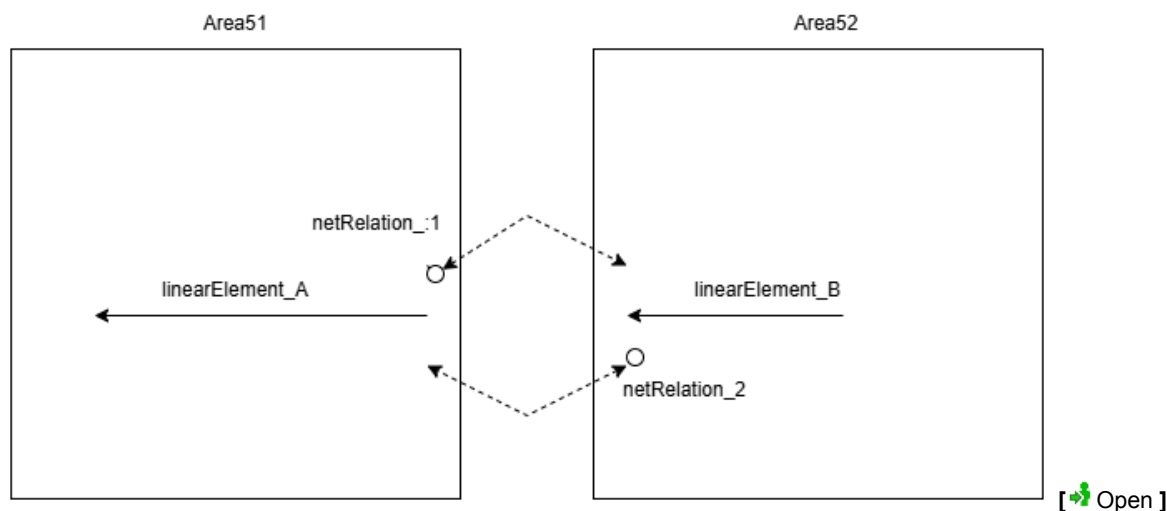

Figure 3 Linking areas

The json-serialisation for this example would be for the "Infrastructure"-object

```
{
  "topoAreas": [
    {
      "id": "Area51",
      "linearElements": [
        {"id": "linearElement_A", "length": 10000}
      ],
      "netRelations": [
        {"id": "link_1", "elementA": "linearElement_A", "elementB": "/1/1[Area52]/2[linearElement_B]", "
isOnOriginOfElementA": true, "isOnOriginOfElementB": false}
      ]
    },
    {
      "id": "Area52",
      "linearElements": [
        {"id": "linearElement_B", "length": 10000}
      ],
      "netRelations": [
        {"id": "link_2", "elementA": "linearElement_B", "elementB": "/1/1[Area51]/2[linearElement_A]", "
isOnOriginOfElementA": false, "isOnOriginOfElementB": true}
      ]
    }
  ]
}
```

As visible from the example, the linking between LinearElements is done twice by two NetRelation-objects. This allows bi-directional navigation and does not introduce any implications on distance-calculation, as the NetRelation has zero length.

Also, the referenced LinearElements from another TopoArea must be referenced with an absolute reference (see [SP T2TS-122407 - Referencing objects](#)).

2.2.3 Supporting containers

Supporting classes are used only as containers for a set of attributes. They don't contain sufficient information on their own, they don't have an ID and cannot be referenced.

2.2.3.1 Topological coordinate

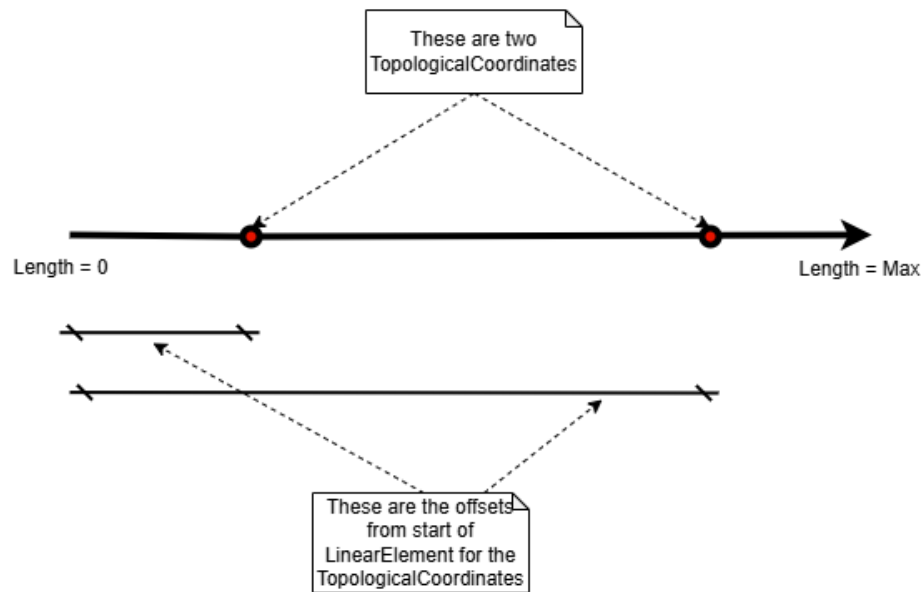

SPT2TS-63854 - A TopologicalCoordinate is a simple supporting container for two attributes: LinearElement-reference and position on it. It does not have an ID and is used only in a composition relation. In most cases a functional object needs only one position-definition (e.g. a Balise). In this cases two separate attributes (trackEdge and pos) are used. In seldom cases an object needs more than one position (e.g. Crossing needs two positions). In this case an array of two TopologicalCoordinates is used.

Figure 4 Illustration of Track Edge Point

Although the TopologicalCoordinate contains similar information as:

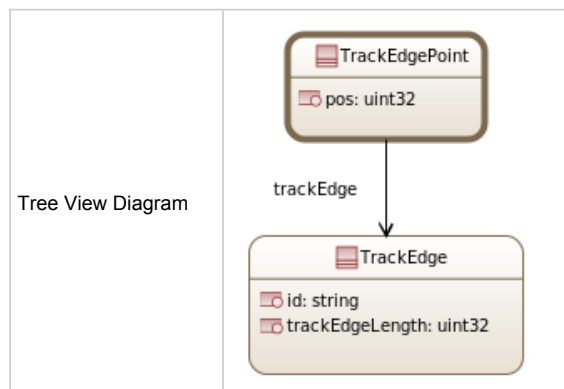

- Spot Location in  SPT2TS-10 - [RSM - RailSystemModel](#)
- Track Edge Point in  SPT2TS-7 - [RCA Digital Map – MAP Object Catalogue \[RCA.Doc.69\]](#)

Its usage is different. In both upper models, the spot locations are defined separately and then used in objects by reference via IDs. Therefore, in both cases, the objects (RSM.SpotLocation and RCA.TrackEdgePoint) use an ID attribute. In this model this level of indirection is avoided, the TopologicalCoordinate cannot be referenced and used directly in a composition relation.

      ]
    }
  ]
}

```

2.2.3.2 Linear Element Section

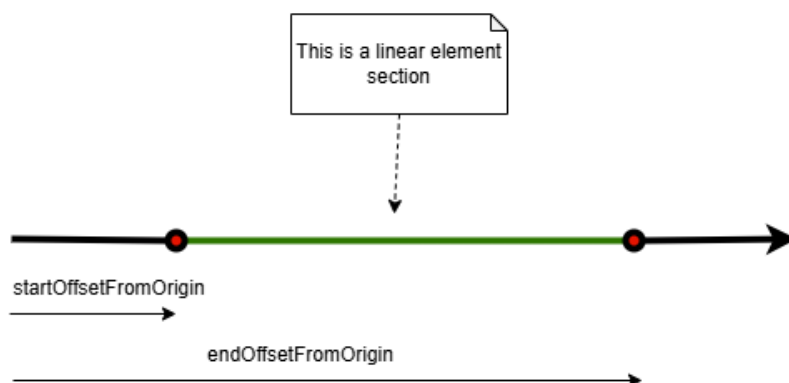

SPT2TS-63855 - A Linear Element Section is a simple container for three attributes defining part of a LinearElement. It is used by other objects as supporting data-object (e.g. TrackEdgeGauges). Linear Element Sections have reference points defined to indicate their start and end locations. The reference points are defined using distance skips from start and end of linear elements. The starting/ending point is to be calculated as a distance increment/decrement from start/end of linear element respectively. Linear Element Section is always limited to one linear element i.e., they cannot be defined over multiple linear elements.

Figure 5 Illustration of Track Edge Section

The following similar classes from other models can be referred to:

- Track Edge Section in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]

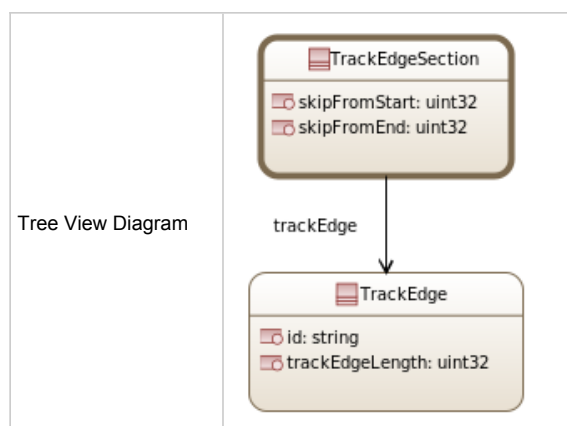

In RCA the TrackEdgeSection is a referenceable object having an ID. It could be defined in a separate container and then re-used in different objects by reference. In this model it is not possible - the infra.LinearElementSection can be used only in a composition relation. When the use case is to define areas (e.g., a contiguous track area or track area) use track edge sections as an attribute with 1..* multiplicity as in  SPT2TS-12698 - TvpSection or  SPT2TS-123558 -

Track Properties .

 In Progress]

TrackEdgeSection

SPT2TS-49081 - LinearElementSection

```
{
  "structs": [
```

```
{
  "name": "LinearElementSection",
  "info": "Defines a directed linear object (with a linear extension) located on a LinearElement",
  "belongsToSubPackage": "FunctionalArea",
  "attrs":[

  ]
}
```

2.2.3.3 NetLinearReference (Linked path)

SPT2TS-63856 - Net Linear Reference defines a continuous path between two given reference points through different interconnected linear elements. The reference points are defined using TopologicalCoordinates. The NetLinearReference is only a container for directed edges, so it does not have an id and is used in other packages in composition-attributes.

Figure 6 Illustration of Linked Path

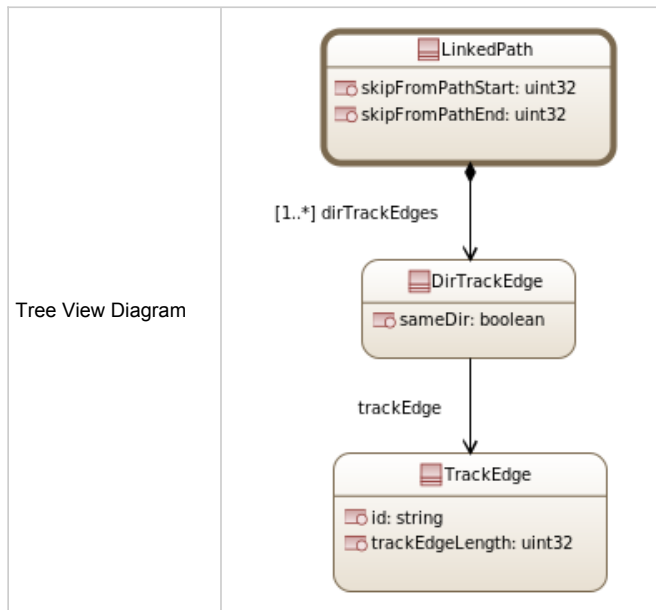

The following equivalent classes from other models can be referred to:

- Linked path  SPT2TS-9 - [LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)
- Linear Contiguous Track Area in  SPT2TS-7 - [RCA Digital Map – MAP Object Catalogue \[RCA.Doc.69\]](#)
- Linear Location in  SPT2TS-10 - [RSM - RailSystemModel](#)

In opposite to RCA and RSM the LinkedPath is not referenceable.

        }
      ]
    }
  ]
}

```

2.2.3.4 NetAreaReference (Track Area)

SPT2TS-127643 - A NetAreaReference groups an arbitrary number of NetLinearReferences. The sections don't have to be connected / adjacent to each other. The Track Area groups the sections to a logical entity, usually to illustrate a technical or functional context.

The abstract concept can be used to define topological extent for the concepts like Area Of Control. E.g., an Area of Control can be of a type Track Area which is defined for a relevant use case.

Figure 7 Illustration for Track Area

The following equivalent classes from other models can be referred to:

- Track Area in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]

```

        }
      ]
    }
  ]
}
```

}

2.2.3.5 Linked Area

SPT2TS-127644 - The Linked Area groups a number of Track Edges and Track Edge Sections, which are topologically connected to each other such that they form one or more paths. The illustrations below show different types of Linked Areas.

Figure 8 Illustration of Track Path

The following equivalent classes from other models can be referred to:

        }
      ]
    }
  ]
}
```

2.3 Track Geometry

SPT2TS-49004 - Track geometry, also known as alignment, defines where the track centre line runs on the surface of the earth. This is typically achieved by defining track centre axes as a sequence of geometric parametric figures, straights, curves, clothoids, etc. It also includes cant definitions. Alternatively, track geometry is given as a suite of points in 3D space that samples the track centre line with an appropriate rate.

Coordinates fixate the track geometry on the surface of the earth and are defined in an appropriate coordinate reference system. [🔗 Content to be approved]

SPT2TS-49003 - The track geometry information is expected to be sufficiently consistent with the real track axis, so it fulfils all criteria of "reliable data".

Reliable Data refers to a typical characteristic of data which satisfies the qualities of being trustworthy/lower probability of incorrect information/lower fault rate of the information, current (not obsolete), complete, and accurate.

Along the life cycle and depending on data availability, several types of geometry are applied:

- design geometry is the idealised geometry as designed in a CAD tool, sometimes called "to-build" or "as-planned".
- as-built geometry describes the geometry as established after track works or tamping.
- as-is geometry is the surveyed geometry, possibly post-processed by the surveyor.

There is maximum (today national specific) tolerances which define the maximum deviation between design geometry (to-build, as-planned) and the real track axes ("as-built"). In addition, this track centre line is restored after each maintenance/tamping procedure. So to achieve maximum robustness and avoid additional error margins (i.e. from dynamical acquisition/surveys) the originally designed track geometry data is assumed to be used.

If this information is not available in a reliable (updated, accurate) way, the track geometry based on surveys ("as-is") is assumed to be used for use cases like ETCS or ATO engineering. However, use cases like maintenance (tamping) will always rely on the desired design situation ("to build").

The track geometry model shall support different levels of details for track description to support the following use cases:

1. Detailed track geometry data for exact track construction, engineering, maintenance or other use cases requiring the actual segments (such as straights, curves, transitions) of track geometry.
2. Approximate track geometry data optimised for efficient transmission and usage in real-time, e.g. for train protection systems or train operation (e.g. ATO segment profile)

[🔗 Content to be approved]

2.3.1 Track Edge Geometry

2.3.1.1 Input models / references

SPT2TS-64091 - The track edge geometry definition follows the definitions from  SPT2TS-10 - RSM - RailSystemModel and  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69] . [🔗 Content to be approved]

2.3.1.2 Design decisions

SPT2TS-49017 -

The track geometry definition shall ensure that the geometric primitive elements are specified for each track edge, because

- it ensures that no backwards search along the track edges is required to identify the specific values (such as gradient, radius, etc.).
- "Breaking up" segments that straddle a track edge is computationally hard and should not be the responsibility of the data consumer.
- Assigning segments to areas and subdividing areas is computationally easier

[🔍 Content to be approved]

SPT2TS-49016 - The track geometry definition shall ensure that the entire extent (0..length) of the track edge is populated with the required geometric primitive elements. [🔍 Content to be approved]

SPT2TS-64092 - The track edge geometry has a list of one or more contiguous, i.e. abutting segments. A track segment is a parametrised geometric figure, i.e. line, arc or transition. [🔍 Content to be approved]

SPT2TS-49014 - The list of segments is ordered from start to end of the track edge. [🔍 Content to be approved]

SPT2TS-49038 - A segment is assigned to exactly one track edge geometry; a segment never straddles two track edges. [🔍 Content to be approved]

SPT2TS-49036 - Redundant transmission of start- and end-values (e.g. position, azimuth, radius,...) is avoided, which reduces data volume and the need to check plausibility by the data receiver (the next segment starts where the previous one ended). Instead,

- Initial values of a segment (e.g. position, azimuth, radius, ..) are always informed.
- Final/end values (e.g. azimuth, radius) of a segment are defined by the initial values of the next segment
- to describe the complete edge, a final segment with length=0 is required to define the end azimuth of a transition curve, if the last track edge ends with a transition curve.

[🔍 Content to be approved]

SPT2TS-49034 - The position along the track p informs where the segment starts (offset). Position p is the distance a train will travel along the 2D projection of the track on a horizontal mapping plane. The 3D projection of the track can be derived depending on the data consumer needs using 2D values and with required corrections. 2D was chosen as compromise to minimise the efforts spent for 3D data provisioning/engineering. [🔍 Content to be approved]

SPT2TS-123551 - The length of a segment is defined by the position of the next segment minus the position of the current segment ($p_{n+1} - p_n$). [🔍 Content to be approved]

SPT2TS-49031 - Azimuth is the clockwise bearing with respect to the geographic north. [🔍 Content to be approved]

SPT2TS-49028 - Cant is commonly expressed as superelevation, i.e. the height difference between the inner and outer rail along the curve because it's a convenient way of acquiring the measure in the field. Defining which is the inner and outer rail can be ambivalent but the left and right rail is well defined when given with respect to the orientation of the track edge. The cant here represents applied cant. [🔍 Content to be approved]

SPT2TS-49025 - The position on a map (coordinates) isn't given (moved to another part of the model) [🔍 Content to be approved]

approved]

SPT2TS-49045 -

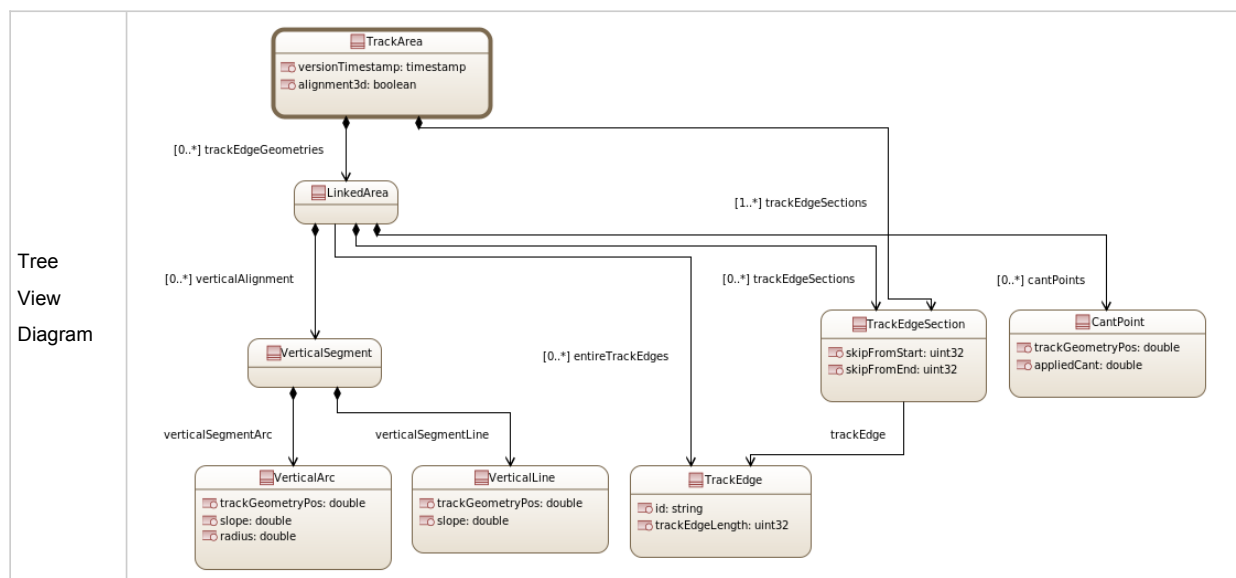

Figure 9 Top view of exact track geometry model. The exact geometry of a track edge is a list of track segments, ordered in the direction of the track edge (right to left in this figure). The position and azimuth of each segment are given.

The following equivalent classes from other models can be referred to:

- Horizontal alignment, Vertical alignment, and Lateral inclinations in  SPT2TS-10 - RSM - RailSystemModel
- Curve, Gradient, and Cant in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]
- Horizontal alignment, Vertical alignment, and Lateral inclinations in  SPT2TS-8 - EULYNX Data Model (dataprep.eulynx.eu)
-  SPT2TS-9 - LinX4Rail CDM ->PSM (Platform Specific Data Model)

2.3.2 Linear Element Sampled Geometry

2.3.2.1 Input models / References

SPT2TS-64093 - The linear element geometry definition follows the definitions  [SPT2TS-9 - LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)

The following equivalent classes from other models can be referred to:

-  [SPT2TS-9 - LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)

[➡ Open]

2.3.2.2 Design Decisions

SPT2TS-49013 - Sampled linear element geometry represents the linear element geometry as a list of sampled discrete points. This is typically used when the exact geometry isn't available or not required for the specific use case (e.g ATO Segment Profile). The sampling rate can't be prescribed but be such as to satisfy current use cases. By increasing the sampling rate (e.g. 10cm sample point distance), a very exact representation is possible as well if needed.

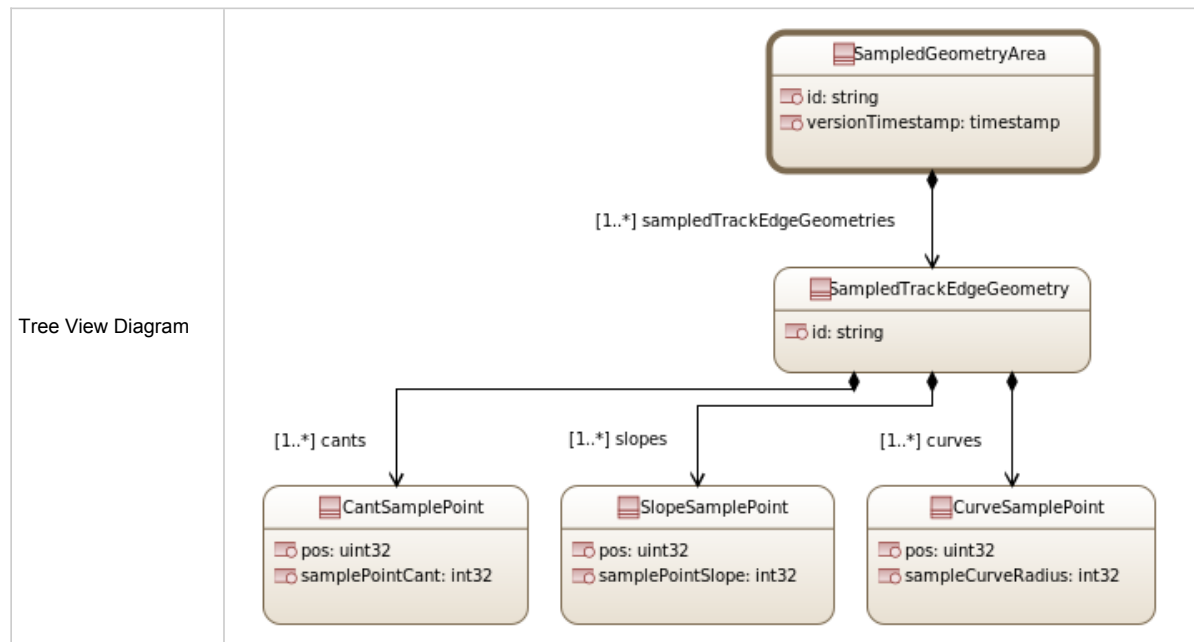

Figure 11: Top view of a sampled track geometry. A track edge is associated with a list of points, each of which is a sample of the track centre line.

[ Open]

SPT2TS-49012 - The decision of Linear Element Geometry (see [SPT2TS-49033 - Design decisions](#)) are also valid for the sampled track geometry, though the amount of information is reduced (e.g. azimuth, slope not required for simple model and not added). [ Open]

2.4 Point, Crossing, Derailer

SPT2TS-63857 - Point, crossing and derailer are track assets / field elements. They contain movable components which are equipped with actuators in order to set / change the positions of the field element.

Points are controlled field elements which represent a branching point in the track network wherein exists a possibility to continue either on the right or on the left branch:

- Simple points (with and without movable frogs)
- Single- and double-slip crossings

In a simple point, a branch track branches off from a main track. A simple point offers two driving possibilities i.e. one along main track and one along the branch track. The required direction of travel can be set using the point machines.

A single or double slip crossing are between two tracks without grade of separation and with possibility to switch between straight passing track and turning track.

Derailer is a safety device attached to a rail, which when operated can cause a derailment of a train that is making an unauthorised movement. A derailer prevents rail vehicles from driving on the track beyond the point secured by the derailer.

Derailers are intended to prevent accidents caused by cold movements, for example rolling of parked rail vehicles which were not secured against unintentional movements.

A track crossing between two tracks without grade of separation and without possibility to switch between straight passing track and turning track. In other words, diamond crossing is the overlapping/intersection of two tracks at the same level without the possibility of changing tracks. There are two possible types of a diamond crossing, one with movable tongues (switched diamond crossing) and one without movable parts (non-switched diamond crossing)

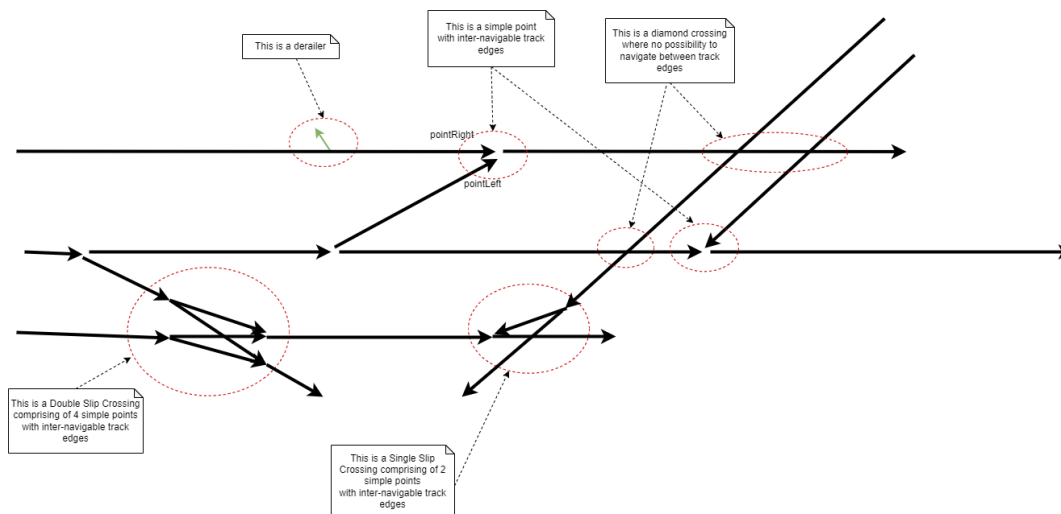

Figure 13 Meaning of attributes in classes

The following equivalent classes from other models can be referred to:

- Point, Crossing, and Derailer in  SPT2TS-7 - [RCA Digital Map – MAP Object Catalogue \[RCA.Doc.69\]](#)
- Crossing, Derailer, Buffer Stop, Rail Switch in  SPT2TS-9 - [LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)
- Crossing and Turnout in  SPT2TS-10 - [RSM - RailSystemModel](#)

[ Open]

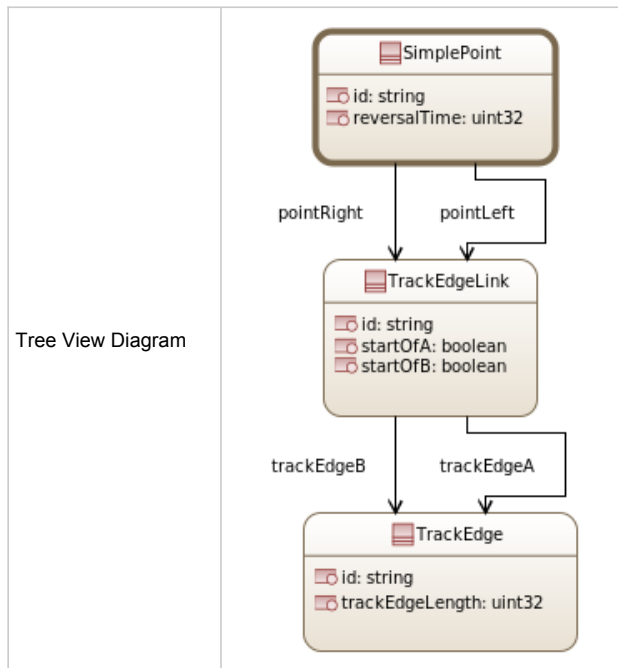

2.4.1 Design Decisions

SPT2TS-123574 - In case of crossing remains the question, how this functional element is represented in the topology Map:

1. without splitting the linear elements (the Crossing-object defines location of the crossing on the linear element)
2. by splitting LinearElement at the crossing and introducing NetRelations with applicableDirection == None.

The first option was selected as much more compact, without loss of information. The crossing in this case contains two TopologicalCoordinates marking the crossing locations on LinearElements, rather than defining a list of NetRelations, which would be the case for second option. [ Open]

SimplePoint

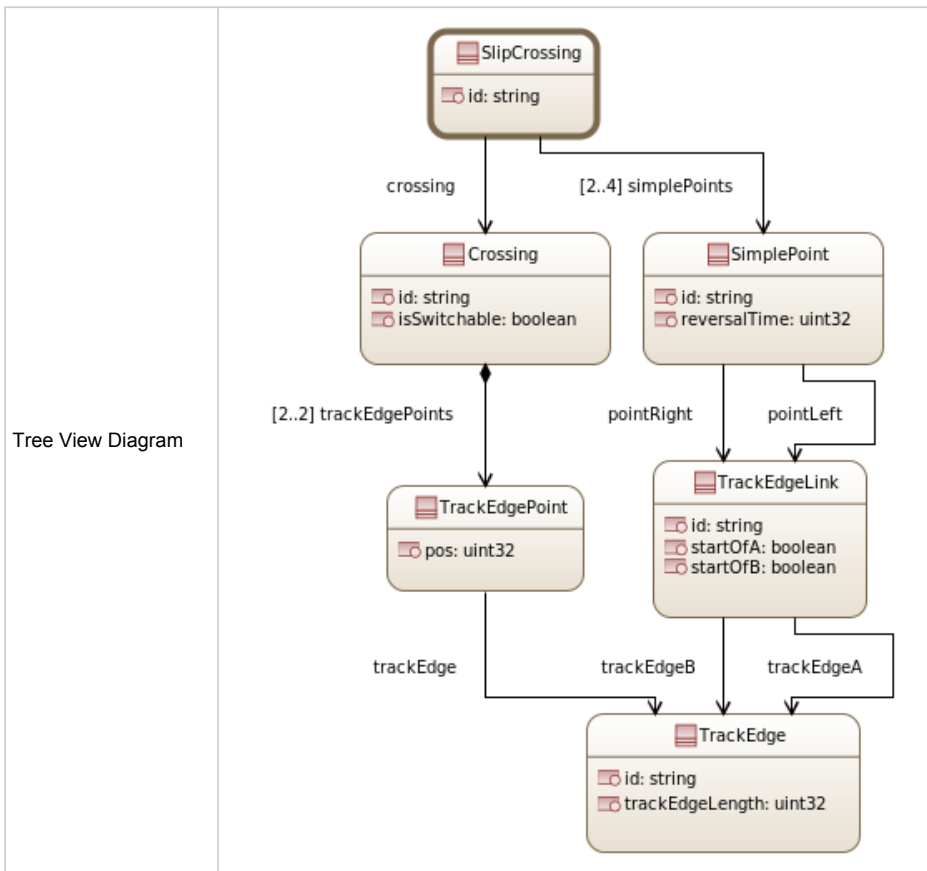

SPT2TS-49048 - Switch (SimplePoint)

2.5 Balise (Group)

SPT2TS-63858 - Balises (or Eurobalises in the context of ETCS) are technical devices on the railway track bed that store information (telegram) and transmit it to rail vehicles passing the location of the Balise. The balises shall be represented using a Track Edge Point on the topology and are not associated with a direction.

Balises are clustered in groups and each balise group can consist a maximum of 8 Balises. Orientation direction of the balises are explicitly provided.

The following equivalent classes from other models can be referred to:

- Balise and Balise Group in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]
- Balise and Balise Group in  SPT2TS-9 - LinX4Rail CDM ->PSM (Platform Specific Data Model)

- Balise and Balise Group in <https://eulynx.eu/index.php/dataprep>

```

2.6 Track Properties

SPT2TS-63859 - Track properties is a container for different classes which define properties for a section of track. The following properties are defined as a part of it:

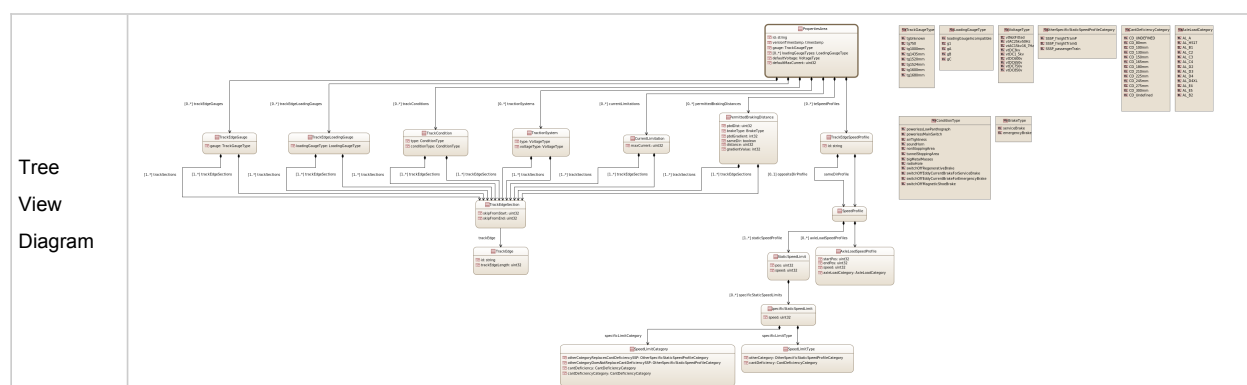

1. Track Condition: Defines the type of the condition valid for a section of track.
2. Track Edge Loading Gauge: Defines the loading gauge applicable for a section of track.
3. Track Edge Gauge: Defines the gauge (i.e., 1000mm, 1435mm, ...) applicable for a section of track.
4. Current Limitation: Defines the applicable current limitation in Amperes for a section of track.
5. Permitted Braking Distance: Defines the permitted braking distance for the train to come to stop before danger areas like Level Crossing, unplanned Radio holes, etc
6. Traction System: Defines the equipped traction system on the track.

The following equivalent classes from other models can be referred to:

- Track Condition, Loading Gauge, Gauge, Traction System, Current Limitation, and Permitted Braking Distance in  [SPT2TS-7 - RCA Digital Map – MAP Object Catalogue \[RCA.Doc.69\]](#)
- Loading Gauge, Gauge, Voltage, Current Limitation, and Permitted Braking Distance in  [SPT2TS-9 - LinX4Rail CDM ->PSM \(Platform Specific Data Model\)](#)

}
```

}

2.8 Speed Profiles

SPT2TS-63860 - Speed profiles represent a base object that defines the speed restrictions for a section of track.

Specific speed profiles are defined as an extension to this base object.

The following different kinds of speed restrictions exist:

1. The Static Speed Profile (SSP) is a description of the fixed speed restrictions of a given section of track. The speed restrictions can be related to, e.g. maximum line speed, curves, points, tunnel profiles, and bridges.
 1. The specific SSP categories, as defined in ETCS Subset 026, are decomposed into two types:
 - The “Cant Deficiency” SSP categories: the cant deficiency value assigned to one category shall define the maximum speed, determined by suspension design, at which a particular train can traverse a curve. It thus can be used to set a specific speed limit in a curve with regard to this category.
 - The “other specific” SSP categories: group all other specific SSP categories corresponding to the other international train categories.
 2. The Axle load speed profiles define restrictive speed profiles for sections of track based on the different axle load categories defined in ETCS Subset 026.

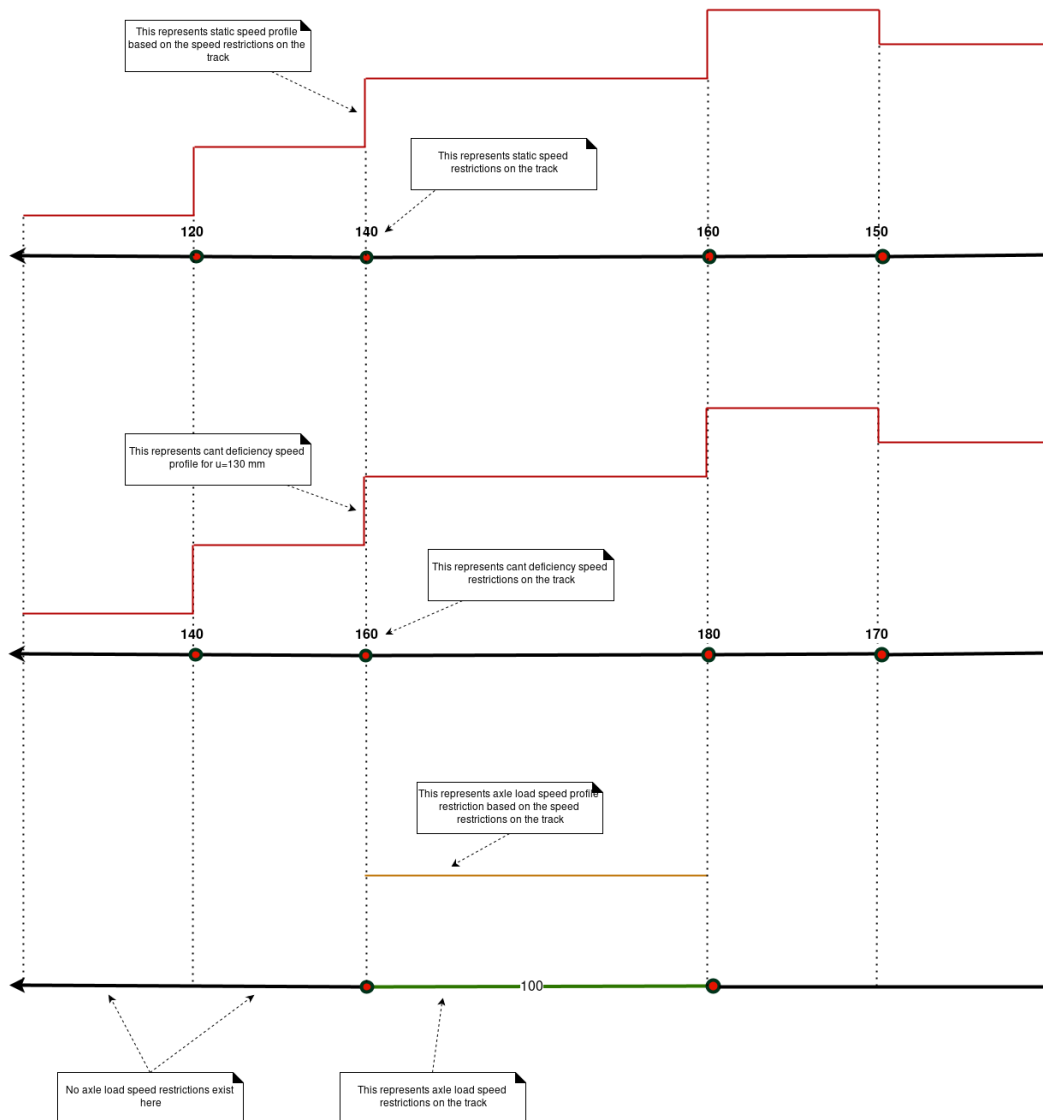

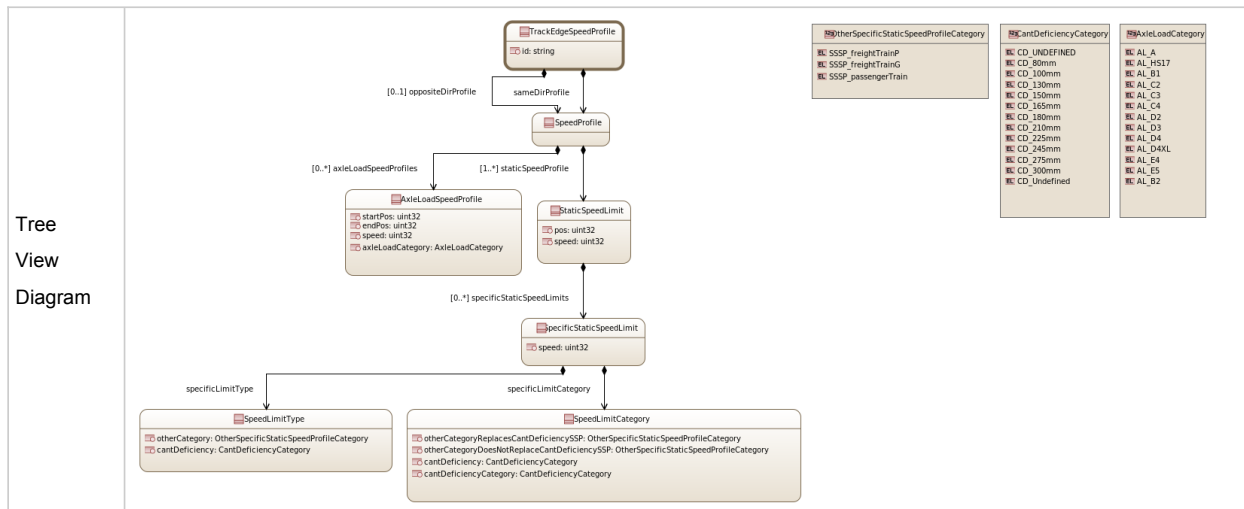

Figure 15 Illustration of different Speed Profiles

```

2.8.1 Applicable direction

The speed profile in the same direction as the LinearElement is assigned to LinearElementSpeedProfile.sameDirSpeedProfile. The speed profile in the opposite direction, if it is different from the "same direction" is assigned to LinearElementSpeedProfile.oppositeDirSpeedProfile. The SpeedProfile is a sampled speed curve, where the speed value defined in some position "pos" is valid in the "increasing" direction. This approach is used for both: same direction and opposite direction speed profiles. If you want to traverse the opposite direction from the End to Begin of the LinearElement ensure proper adjustment of the speed-change-positions.

Figure 16 Speed profile in opposite direction.

The data object representing the speed profile for the opposite direction:

```

{
  "trackEdge": "trackEdge_1",
  "oppositeDirProfile": {
    "staticSpeedProfile": [
      {"pos": 0, "speed": 100},
      {"pos": 1000000, "speed": 50},
      {"pos": 5000000, "speed": 100}
    ]
  }
}

```

This means, that in the section [5000, 8000] the speed 100 is valid for trains moving in opposite direction of the trackEdge_1.

2.9 ETCS Marker

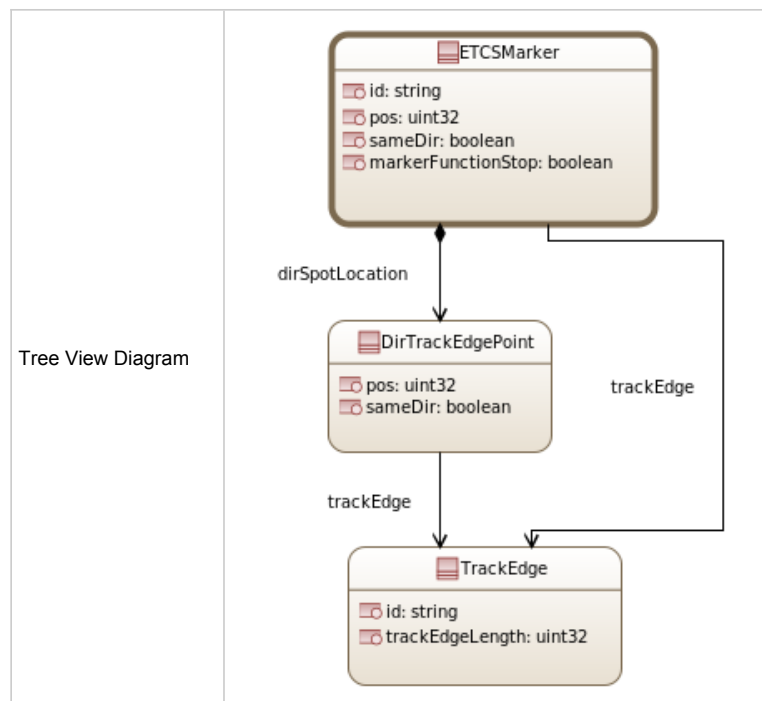

SPT2TS-64095 - Defines ETCS stop and location markers.

The following equivalent classes from other models can be referred to:

- Signal in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]

[ Open]

ETCSMarker

SPT2TS-49088 - ETCSMarker

```

2.12 Operational Point

SPT2TS-63863 - An operational point is an area of the railway network, aggregated into a geographical point (with geographical coordinates), that has a distinctive operational function.

Note:

1. Although an Operational Point is illustrated as an area, it is merely just a set of characteristics belonging to a particular location.
2. The centre point is not always located in the centre of the operational point, and corresponding tolerances can be foreseen.

Use Case: Systems which are responsible for planning railway operations might require an overview on this level to determine required points (specific to an operational point) on the topology for timetable planning, journey profile definition, movement permission definition, etc.

The illustration below depicts an Operational Point with its operational characteristics. The definition of Operational Point might not be apt, and it is only defined for pictorial and understanding purposes.

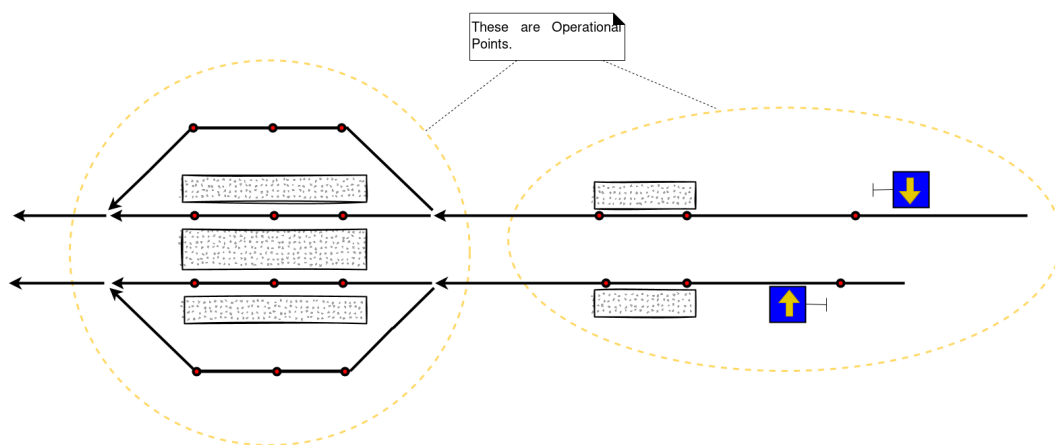

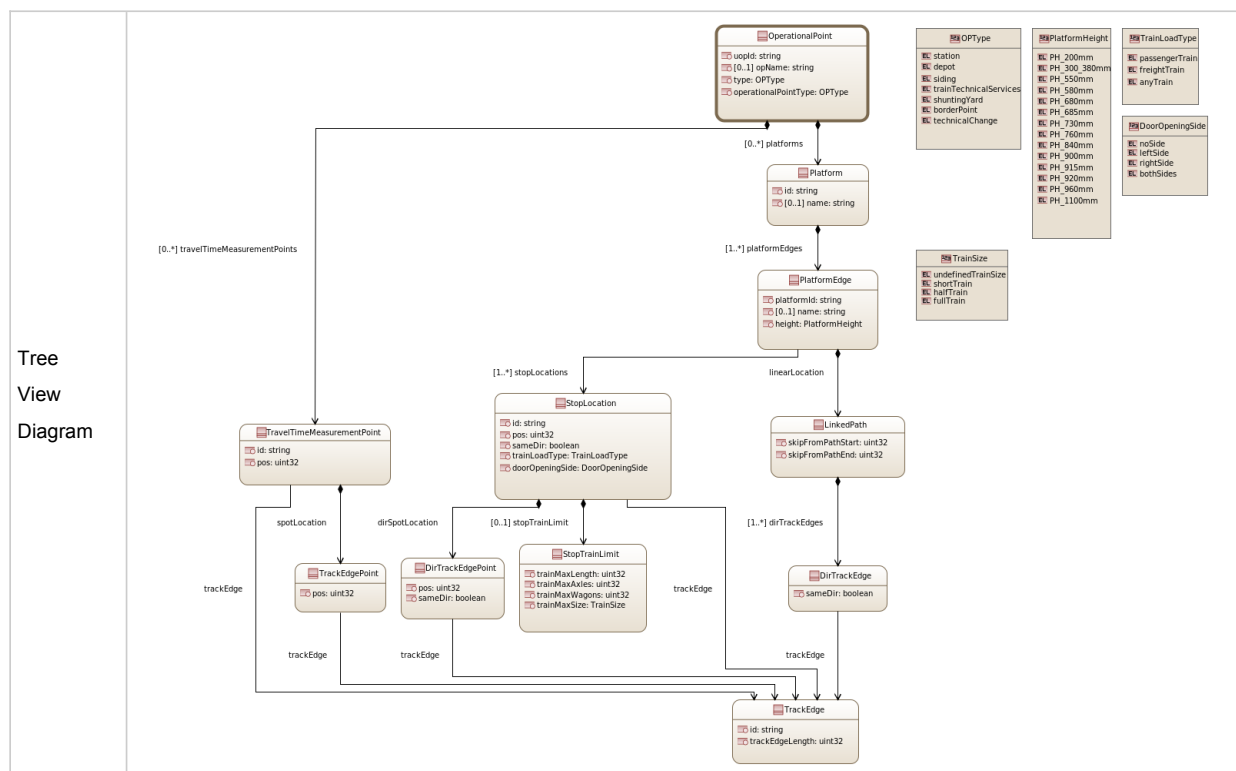

Figure 17 Explanation for Operational Points

The following equivalent classes from other models can be referred to:

- Operational Point in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]
- Operational Point in  SPT2TS-64108 - Guide on the application of the common specifications of the register of [Infrastr...](#)

```

2.13 Timing Point

SPT2TS-63864 - A Timing Point is an ATO-aspect. It is a fixed point on the infrastructure which is associated with the appropriate time. This time may be an arrival time, departure time, or a passing time.

The fixed points on the infrastructure can be further elaborated as follows:

- All the ETCS signals where the routes may end or begin and at signals covering danger areas, e.g., tunnels or buffer stops.
- At platforms, e.g., In the center and both ends of the platform
- At stop posts, e.g., based on train lengths (200m, 300m, ...), train size (short, medium, full), Number of Wagons, Number of Axles

In addition, the Timing Points have stopping accuracy information i.e., tolerances which enable trains to come to an accurate stop at Timing Points. To ensure precise stopping, additional requirements on the engineering of balises before Timing Points of relevance are also foreseen.

Use Case: For ATO, Timing Points are referenced in Segment Profiles and Journey Profiles. The Segment Profiles provides the location of the Timing Point and the Journey Profiles provide the time and operational aspects (Stop/Pass/Skip) of the Timing Point. The illustration below depicts a Timing Point with respect to Operational Points.

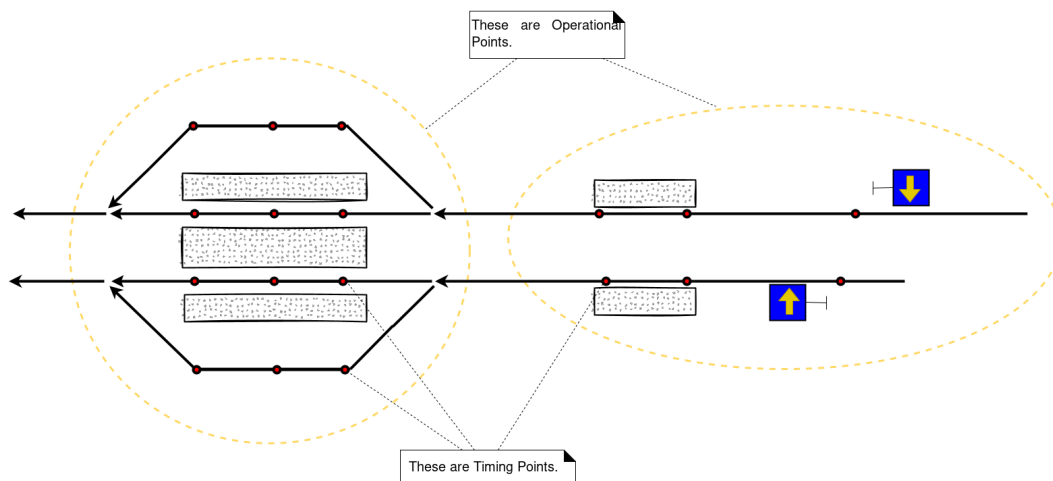

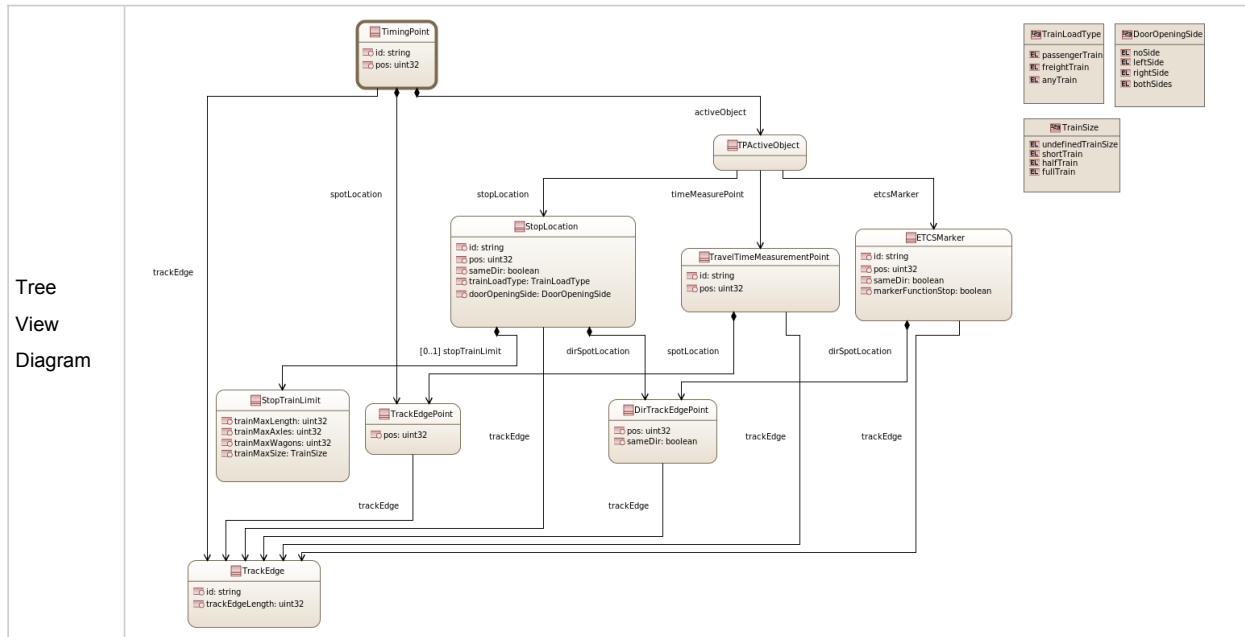

Figure 18 Explanation for Operational Points and Timing Points.

The following equivalent classes from other models can be referred to:

- Timing Point in  SPT2TS-7 - RCA Digital Map – MAP Object Catalogue [RCA.Doc.69]
